3 Examples.....	3

1. Description

Load object data from a file into the project model on the server.

The load-objects command provides the capability to read type instance data from a file and load it into the active project model running on the server.

Each type's module directory can contain an `objects` sub directory where files containing object data can be stored.

static: This command can be run outside of an object context.

2. Usage

```
ctl -m ProjectBuilder -c load-objects [-basedir <>] [-basetype
<>] [-delimiter <:>] [-filename <>] [-format <projectxml>]
[-type <all>]
```

2.1. Options

Option	Description	Type	Default
basedir	<i>dir containing modules</i>	string	<code>\${entity.attribute.basedir}</code>
basetype	<i>specifies the basetype of object data</i> If type is not specified but filename is, type will default to base of the <code>\${opts.filename}</code> argument minus the extension.	string	
delimiter	<i>field delimiter. Only relevant if format is tabular. Defaults to ":" (colon)</i>	string	:
filename	<i>filename containing object data</i> If filename is not specified but type is, filename will default to <code>\${opts.type}.tab</code>	string	

format	<i>data format. Either "tabular" or "projectxml".</i>	string	projectxml
type	<i>type name</i> If type not specified, the object data for all types in basedir will be loaded	string	all

3. Examples

The example below shows setting data being loaded on to the server.

The first example loads data defined as project XML format. Here a single file containing many object definitions of mixed type can be supplied to the load-objects command as follows:

```
ctl -p project -m ProjectBuilder -c load-objects -- -format projectxml
-filename PathToFile
```

Alternatively, the tabular format can be used:

```
ctl -p project -t ProjectBuilder -o object -c load-objects --\
-type TypeX -format tabular -filename setting.tab -basetype
setting
```

Load-objects can default option values depending on other existing args. For example, if the file base is called *setting* the resource type will automatically be set to that. The reverse is also true. For example:

```
ctl -p project -t ProjectBuilder -o object -c load-objects --\
-type TypeX -format tabular -filename setting.tab
```

vs.

```
ctl -p project -t ProjectBuilder -o object -c load-objects --\
-type TypeX -format tabular -basetype setting
```

If all object data files should be processed, one can leave out both options:

```
ctl -p project -t ProjectBuilder -o object -c load-objects -- -type TypeX
```
